Formal definition

A finite state transducer is a tuple $(\Sigma_i, \Sigma_o, Q, q_0, F, \Delta)$

 Σ_i is the *input* alphabet

 Σ_0 is the *output* alphabet

Q a finite set of states

 $q_0\,$ is the start state, $q_0\in Q$

 ${\sf F}\,$ is the set of accepting states, ${\sf F}\subseteq {\sf Q}\,$

 Δ is a relation $(\Delta : Q \times \Sigma_i \to Q \times \Sigma_o)$

Introduction Operations on FSTs Determinizing FSTs Sur

Where do we use FSTs?

example 1: morphological analysis

In this lecture, we treat an FSA as a simple FST that outputs its input: edge label 'a' is a shorthand for 'a:a'.

Closure properties of FSTs

Like FSA, FSTs are closed under some operations.

- Concatenation
- Kleene star
- Complement
- Reversal
- Union
- Intersection
- Inversion
- Composition

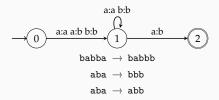

Finite state transducers

A quick introduction • A finite state transducer (FST) is a finite state machine where

transitions are conditioned on a pair of symbols • The machine moves between the states based on input symbol, while it outputs the corresponding output symbol

ions on FSTs Determinizing FSTs Sum

- An FST encodes a *relation*, a mapping from a set to another
- The relation defined by an FST is called a regular (or rational) relation

Uses in NLP/CL

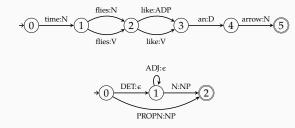

- Morphological analysis
- Spelling correction
- Transliteration
- · Speech recognition
- Grapheme-to-phoneme mapping
- Normalization
- Tokenization
- POS tagging (not typical, but done)

Where do we use FSTs?

example 2: POS tagging / shallow parsing

Note: (1) It is important to express the ambiguity. (2) This gets interesting if we can 'compose' these automata.

FST inversion

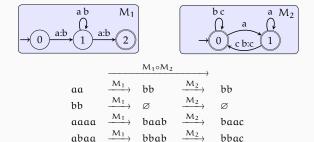

- · Since FST encodes a relation, it can be reversed
- Inverse of an FST swaps the input symbols with output symbols
- We indicate inverse of an FST M with M⁻¹

FST determinization

- A deterministic FST has unambiguous transitions from every state on any *input* symbol
- We can extend the subset construction to FSTs
- Determinization often means converting to a *subsequential* FST
- However, not all FSTs can be determinized

Sequential FSTs

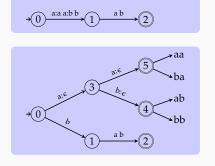

- · A sequential FST has a single transition from each state on every input symbol
- · Output symbols can be strings, as well as ε
- The recognition is linear in the length of input
- · However, sequential FSTs do not allow ambiguity

Introduction Operations on FSTs Determinizing FSTs Summary

FSA vs FST

- FSA are acceptors, FSTs are transducers
- FSA accept or reject their input, FSTs produce output(s) for the inputs they accept
- FSA define sets, FSTs define relations between sets
- FSTs share many properties of FSAs. However,
 - FSTs are not closed under intersection and complement
 - We can compose (and invert) the FSTs
 - Determinizing FSTs is not always possible
- Both FSA and FSTs can be weighted (not covered in this

Subsequential FSTs

- up to k strings at an accepting state
- · Subsequential transducers allow limited ambiguity
- · Recognition time is still linear

- The 2-subsequential FST above maps every string it accepts to two strings, e.g.,
 - baa \rightarrow bba
 - $baa \rightarrow bbbb$

Another example

Can you convert the following FST to a subsequential FST?

Note that we cannot 'determine' the output on first input, until reaching the final input.
